HEALTH STATISTICS

FROM THE U. S. NATIONAL HEALTH SURVEY

Hospital Discharges and length of stay: short-stay hospitals

United States 1958 - 1960

Statistics for short-stay hospitals on patients discharged and days of hospital stay by selected characteristics of the patients and types of hospitals. Based on data collected in household interviews during July 1958-June 1960.

The U. S. National Health Survey is a continuing program under which the Public Health Service makes studies to determine the extent of illness and disability in the population of the United States and to gather related information. It is authorized by Public Law 652, 84th Congress.

CO-OPERATION OF THE BUREAU OF THE CENSUS

Under the legislation establishing the National Health Survey, the Public Health Service is authorized to use, insofar as possible, the services or facilities of other Federal, State, or private agencies.

In accordance with specifications established by the National Health Survey, the Bureau of the Census, under a contractual arrangement, participates in most aspects of survey planning, selects the sample, collects the data, and carries out certain parts of the statistical processing.

HOSPITAL DISCHARGES

INTRODUCTION

In the United States there are approximately 115 discharges from short-stay hospitals in a year among every 1,000 persons alive at the end of the year. These figures refer to the civilian noninstitutional population. The rate of hospital discharges among females, 140.9 per 1,000 persons, exceeds that for males, 87.5 per 1,000 persons. Even when hospitalization for deliveries is excluded the hospitalization rate for females (99.4 per 1,000) is greater, but the excess is confined to the ages between 15 and 54 years.

Excluding deliveries, the rate of hospitalization increases with age from 55 discharges per 1,000 children of ages 5-14 to 154 per 1,000 persons aged 75 years and over. Similarly, the average length of hospital stay increases with age, ranging from 4.7 days to 15.8 days per episode for the age groups mentioned.

This report includes hospitalization data by age, sex, geographic region, race, income, and other characteristics of the population, It is based upon data obtained in health interviews during the period July 1958 through June 1960. An earlier report from the U. S. National Health Survey, Series B, No. 7, for the year July 1957 through June 1958, included similar data on hospitalization. However, the two reports are not suitable for trend analysis because, in this report several changes have been made which influence the estimates presented. The most important processing innovation is the use of a six-monthrecall period instead of the one-year-reference period used in the earlier report (B-7). A further change is the presentation of average annual estimates based on two years of data collection. The increased stability gained by extending the collection period is offset somewhat by reducing the recall period to six months. These processing methods are explained in more detail later in the text and in Appendix I.

SOURCE AND QUALIFICATION OF DATA

The Health Interview Survey derives data from a continuous probability sampling of the civilian, noninstitutional population of the United States. The tables in this report present estimates of the number of hospital discharges and number of hospital days for patients discharged from short-stay hospitals in the United States. The data were collected in approximately 75,000 households, comprising 245,000 persons, during the two-year-interview period.

During each of the 104 weeks during the two-year period interviews were conducted in a different sample of households. In addition to information on other health and demographic characteristics, the hospitalization experience of household members for the 12 months prior to the week of interview was obtained, Methodological studies conducted by the National Health Survey relating to the reporting of hospital experiences in interview surveys indicate that information reported for the most recent six months of a one-year-recall period tends to be more accurate than that reported for the earlier part of the reference period. Therefore, in the processing of the data the hospital experience reported for individuals during the 6-month period immediately preceding the week of interview was adjusted to serve as a basis for the estimated annual number of hospitalizations.

Each of the 104 weekly samples obtained during the interview period, July 1958-June 1960, provides an independent estimate of the hospital experience for the population during the previous six months. Therefore, averaging of these 104 weekly samples yields an estimate of the hospital utilization during an average six-month period. Multiplying this estimate by two yields an average annual estimate which is based on hospital experience reported during the interview period, July 1958-June 1960, for discharges occurring between January 1958 and June 1960.

Additional detailed information about the methods employed for producing these estimates,

This report was prepared by Kenneth W. Haase of the U. S. National Health Survey staff.

a description of the statistical design of the household survey, and general qualifications of the data presented in this report are given in Appendix I. All estimates in this report are based on information obtained from a sample of the population rather than from the entire population, and are therefore subject to sampling error. Particular attention should be given to the section entitled "Reliability of Estimates" which includes sampling error tables and instructions for their use.

A general limitation of all data obtained by household interviews is that the data are no better than the respondent's knowledge and ability to recall the correct answers to specific questions. As discussed earlier in this report, using only those hospital experiences occurring during the most recent six months prior to interview as a basis for the annual estimate reduces bias due to faulty memory.

Hospital discharges of inpatients who were not hospitalized for at least one night have been excluded. Therefore, the estimates produced are less than those which may be obtained by means of hospital records of all discharged patients. Some indication of the proportion of inpatients who do not remain in the hospital overnight was obtained by the Indiana Experimental Hospital Morbidity Study for 1960, conducted by the State Board of Health of Indiana. In this study it was found that of 11,159 inpatients in the sample, 2.7 percent were discharged on the same day they were admitted.

Definitions of a hospital discharge and of other terms used in this report are given in Appendix II. Since many of these terms have specialized meanings for the purposes of this survey, familiarity with these definitions will assist the reader in interpreting the data.

Questions 21 and 22 in figure 1 are designed to obtain from the respondent information as to whether or not members of the household have been in any type of institution defined as a hospital according to the survey. Question 22 was not intended for the purpose of estimating the volume of care in nursing homes or sanitariums. It was included only to elicit information on episodes in establishments which are

Figure 1.

in fact hospitals as defined by the Health Interview Survey, but which otherwise might not have been reported because respondents did not consider the establishment as a hospital.

An entry is made in each of the columns of table II for every episode of hospitalization that is reported in response to the hospitalization-recall questions.

The information obtained in table II permits the identification and counting of admissions, discharges, and number of days of hospital stay. Column (h) provides the reason for hospitalization. If the respondent reported more than one condition, each condition was recorded. During the coding process however, the condition which was believed to have contributed the major portion of the hospital stay was selected for tabulation. The coding was done in accordance with the International Classification of Diseases, 1955, as modified for use in the Health Interview Survey. All operations were recorded in column (i).

Column (j) in the questionnaire serves several purposes. First, it makes it possible to determine if the institution reported is one that meets the definition of a hospital used in this survey (see Appendix II). In case the institution named is not a hospital, the reported event is excluded from the statistics. If the institution is defined as a hospital, it is then classified as to type of ownership, type of service, and whether or not it is a short-stay hospital.

The entire questionnaire is reproduced in Appendix III so the reader may understand the context in which the hospital data were collected. This questionnaire is the one used during the interview period of July 1958 to June 1959.

DISCHARGES FROM SHORT-STAY HOSPITALS

All data presented in this report are based on estimates of the average annual number of hospital discharges and the number of hospital days for patients discharged from short-stay hospitals. They exclude discharges and days for persons who died during the year prior to the interview. As might be expected, this exclusion makes a considerable difference in the older age groups but much less difference at the younger ages.

Discharges, Hospital Days, and Lengthof-Stay Intervals by Age and Sex

During the period covered by the interviewing there was an average annual estimate of 19,875,000 patients discharged from short-stay hospitals. The total hospital stay for these patients amounted to 166,935,000 days. Table 1 presents these estimates by sex and age. Table 2 presents the same information but excludes hospitalized deliveries so that more meaningful comparisons of discharge rates for males and females can be made. In delivery cases, only the departure of the mother from the hospital was considered as a discharge; a newborn, well infant was not included as a hospital discharge. For this report deliveries are limited to the ages 15 to 54 years.

Table A, which shows the number of discharges and hospital days for deliveries, has been presented in order to give the reader some indication of the proportion of deliveries in those

tables where they have not been excluded from the data. The number of deliveries presented in this table, 3,681,000, is less than the 4,159,000 hospital births reported by the National Vital Statistics Division for the calendar year 1959, There are several factors that may account for this difference. Of major consideration is that only those deliveries occurring in establishments that met the more restrictive definition of a hospital (see Appendix II for definition of "Short-Stay Hospital") were included in Health Interview Survey data, while National Vital Statistics Division considered as a hospital birth all births that occurred in any establishment that provided inpatient care. The figure produced by National Vital Statistics Division is a count of all births occurring in hospitals, whereas the Health Interview Survey estimate is based on the number of women who are hospitalized for delivery, with the result that multiple births are recorded as a single delivery. Furthermore, since Health Interview Survey data refer only to persons alive at the time of interview, the hospital experience of women who died during or subsequent to delivery are not included in the estimate for deliveries. In addition the total number of discharges for deliveries as shown in table A is slightly less than the number of deliveries shown as a category of surgical operations in table 25. This is due to the assignment to the discharge of only the major condition causing the hos-

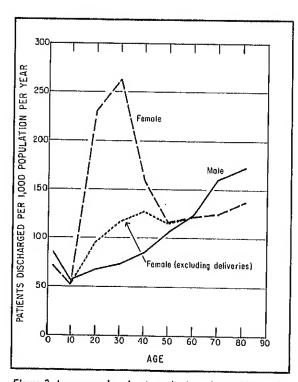

Figure 2. Average number of patients discharged per 1,000 population per year by sex and age.

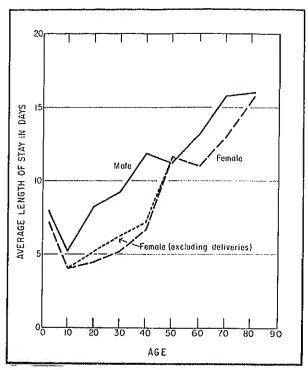

Figure 3. Average length of hospital stay for patients discharged by sex and age.

pitalization when multiple conditions were present, while several surgical procedures may be assigned to a single discharge.

The exclusion of deliveries from the data not only decreases considerably the number of discharges (fig. 2) but also increases the average length of stay (fig. 3) for the female population in the childbearing age groups. This is due to the comparatively short length of hospital stay for deliveries in relation to other hospitalized conditions.

Although the rate of hospital discharges per 1,000 population is higher for females (99.4) than it is for males (87.5) even after deliveries have been excluded, the average length of stay for males is 2.1 days longer than the average length of stay for females. Certain conditions which generally require different lengths of stay tend to occur more frequently in a particular sex group as shown in tables 19 and 20. The number of female discharges for all genitourinary system conditions, excluding deliveries, was 1,681,000 with an average length of stay of 5.7 days. while the number of male discharges for all genitourinary system conditions was only 590,000 with an average length of stay of 10.8 days. On the other hand, heart disease, which is characterized by a relatively long length of hospital stay, was more common among males, 383,000 discharges with an average length of stay of 17.2 days. For females there were 292,000 discharges involving heart conditions with an average length of stay of 15.1 days.

Of the total patients discharged from shortstay hospitals, 57.8 percent had a length of stay of less than 6 days, and 88.4 percent stayed less than 15 days (table 3). The length of stay increased markedly with age. Of the 2,183,000 discharged patients aged 65 years and over, 28.1 percent had a length of stay of 15 or more days as compared with 13.7 percent for all ages when deliveries are excluded.

Table 4 presents the average annual number of hospital days by length-of-stay interval according to age and sex, including and excluding deliveries. The increased length of stay among older persons is also apparent in this table. Of the total number of hospital days for persons 65 years and over, 66.1 percent were associated with hospital stays of 15 or more days as compared with 47.8 percent for persons under 65 years of age (excluding deliveries).

Geographic Region and Residence

The estimated number of hospital discharges per 1,000 population as presented in table 5 shows some degree of variation among the four regions of the United States. This variation in regional estimates, although present to some extent for males, is evident to a greater degree for the female population (fig. 4). Variation in aver-

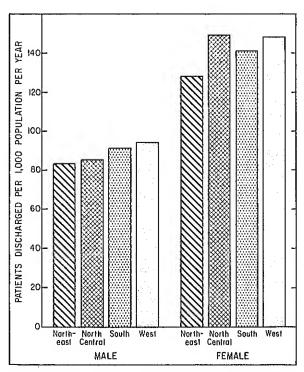

Figure 4. Average number of patients discharged per 1,000 population per year by region and sex.

age length of hospital stay is also present among regions, with length of stay ranging from 7.3 days in the South to 10.2 days in the Northeast (table 6).

Hospital utilization varied considerably by area of residence (tables 7 and 8). Expressed as a rate per 1,000 population the number of discharges for both sexes was 95.6 in rural-farm areas, 115.0 in urban areas, and 122.8 in rural-nonfarm areas. The rate of hospitalization was lower in rural-farm areas than in other areas of residence for both males and females with most of the age-sex groups reflecting this lower rate. The average length of hospital stay was higher in urban than in rural-farm and nonfarm areas, with the hospital stays for males and females both contributing to this difference.

An explanation of these regional and residential variations in the number of hospitalizations as well as in the average length of stay would require a detailed study of social and economic differences, hospital accessibility, and other related factors.

Social and Economic Characteristics

There is considerable difference in the degree of hospital utilization between white and nonwhite persons. In terms of discharges per 1,000 population, the rate for white persons, 117.8, was higher than that for the nonwhite population, 92.2 (table 9). Only in the female age group 15-24 years did the nonwhite rate match that of the white rate. There appears to be less difference in the rates of hospitalization of white and nonwhite persons between ages 15 and 44 than at younger or older ages. For females this may be due to the relatively large proportion of deliveries in this age range, for which hospitalization is common practice in both racial groups. The average length of hospital stay for the nonwhite population, 9.2 days, was longer than that for the white population, 8.3 days (table 10).

Differences in rates of hospitalization in the white and nonwhite populations cannot be explained as simply differences in health characteristics; they are also associated with a number of social and economic factors of a complexity beyond the scope of this report.

Family income as presented in tables 11 and 12 can be employed as a measure of economic status only in a very general sense. These tables, which show hospital discharges, hospital days, and average length of stay by amount of family income, do not take into consideration the size of the family, the amount of incurred expenses, and other factors which affect the economic status of the family.

Since many studies have shown that a definite relationship exists between income and education. table B has been prepared to show the number of hospital discharges and days by family income and education. Within each of the two broad family income groups the number of hospital discharges per 1,000 population was lower for persons whose head of family had less than 9 years of education than for those where the head of the family had 9 or more years of education. However, the average length of stay was longest for persons whose head of family had less than 9 years of education for both of the income groups shown. When analyzing the relationship between family income and any measurement of health it must be kept in mind that low family income may be either the cause or the result of poor health.

The rate of discharges per 1,000 population for persons who are reported as "keeping house" was markedly higher than the rate for other usual activity status groups (table 13). Since the "keeping house" group consists primarily of married females, the large number of discharges for delivery in this group is primarily responsible for the high rate of hospitalization.

The number of discharges per 1,000 persons classified as "other" activity status was 248.1

for the age group 65 years and over. A large proportion of persons reported as "other" in the older age groups were persons who were probably too ill to work but were not reported to be retired.

The number of hospital days and the average length of stay by usual activity status is presented in table 14. The average length of stay for women reported as "keeping house" was 0,6 days longer than it was for women reported as "usually working." This longer average length of hospital stay for the "keeping house" group occurred in spite of the fact that most of the hospitalizations for delivery, which have comparatively short average length of stay, were in the "keeping house" group. An explanation is that women reported as "keeping house" generally remain in this category throughout life while the "usually working" persons as they become older move into the "retired" or "other" categories. Hence, a proportionally larger number of the "keeping house" group are found in the older age groups. Other data from the National Health Survey indicate that age for age the working population is a select group with respect to health.

The average annual number of patients discharged and hospital days by household composition are presented in tables 15 and 16. The

Table B. Average annual population, number of patients discharged, and number per 1,000 population; average annual number of hospital days and average length of stay by known family income and education of family head: discharges from short-stay hospitals, United States, 1958-1960

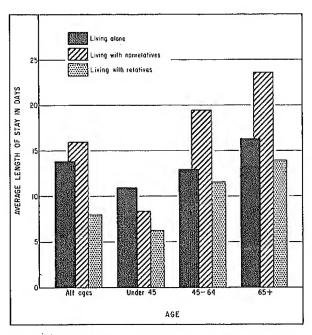

Figure 5. Average length of hospital stay for patients discharged by household composition and age.

extent of hospital utilization as illustrated in figure 5 shows a definite relationship to living arrangements. Persons who lived in households which contained no persons related to them tended to have higher rates of hospital discharges and also remained in the hospital for a much longer time than did persons who lived with relatives.

One of the major reasons for the lower hospital utilization rate for the "living with relatives" group is that it contains almost all of the population under the age of 15, and this group has the lowest rate of hospital utilization. On the other hand the "living with relatives" group accounts for most of discharges for delivery. Table C illus-

trates the effect that the exclusion of deliveries has on the data relating to females aged 15 to 44. When deliveries are excluded, the rate of discharges per 1,000 population is very similar for females living with relatives and for those living with nonrelatives for the age group 15 to 44. The average length of stay changes very little with the exclusion of deliveries.

The high rate of hospital utilization among persons living alone or with nonrelatives may have been due to their being in a less favorable position for receiving proper care at home when they were ill.

Persons 65 years of age and over who were reported as living alone had a lower rate of hospital discharges than persons of the same age in the other two categories of household composition. A possible reason for this difference is that persons who are 65 years and over and living alone could be expected to be in relatively good health. Aged persons who may at one time have lived alone would attempt to change their living arrangements when they became ill.

Hospital Ownership and Type of Service

Table 17 presents the average annual number and percent distribution of hospital discharges and days by type of hospital ownership according to sex. The reader should keep in mind that these statistics relate only to shortstay hospitals. The number of days of hospitalization in governmentally owned hospitals is estimated at 26.7 percent of the total days in short-stay hospitals (table 17). If long-stay hospitals were included, the percentage of days in government hospitals would be substantially higher because of the high proportion of mental, tuberculosis, and other chronic illness hospitals under government ownership,

The average length of stay is long in Federal hospitals and particularly in those operated

Table C. Average annual number of patients discharged, number per 1,000 population, and average length of stay for females 15-44 years of age, excluding deliveries, by household composition: United States, 1958-1960

	Females 15 to	44, excluding	deliveries

	83	106.4	9.9
	3,819	112.7	6.2

by the Veterans Administration. The average length of stay per discharge from veterans hospitals is an estimated 41.2 days as compared with 8.4 days for all hospital discharges. It is possible that veterans often go to local hospitals for minor illnesses when the expected expense is relatively small or covered by insurance, but are likely to use hospital facilities provided by the Veterans Administration when a long and expensive period of hospitalization is anticipated. There are many other factors such as age, types of conditions, and lack of facilities for care at home which affect length of stay in government hospitals as compared with nongovernment hospitals.

Data on hospitalization by type of service are presented in table 18. "Type of hospital service" refers to the predominant type of cases for which the hospital provides care, and not necessarily the type of service received by the patient (see Appendix II for the definition of "type of hospital service"). This explains the hospital discharges of a small number of males from maternity hospitals. These may be staff personnel, emergency cases, or male infants retained beyond normal date of discharge due to some illness or condition.

Condition for Which Hospitalized

The average annual number of discharges and days by condition for which hospitalized and sex is presented in tables 19 and 20. Since these tables are based on discharges from short-stay hospitals, the rates shown represent only a part of the total hospitalization for conditions such as mental disorder, tuberculosis (included in the "infective and parasitic diseases" category), and certain other degenerative conditions for which patients are usually hospitalized in long-stay hospitals or institutions. However, in recent years an increasing number of general hospitals provide some facilities for mental conditions. This increase is reflected in the estimated 407,000 patients hospitalized for "mental and personality disorders" that were discharged from short-stay hospitals.

These conditions are not shown according to age in the detailed tables because such detail for many conditions would contain estimates of very low volume in certain age groups, and therefore subject to high sampling error. For this reason, conditions have been arranged in a few major groups and presented in tables according to appropriate age groupings (tables D, E, and F). Table D contains a list of conditions that occur frequently in all age groups. Table E includes those conditions which occur more

frequently in persons under 45 years of age. Table F includes those conditions most common to persons in age groups 45 years and over. Several factors should be kept in mind in interpreting the data in these tables. Within some of the broad classes of conditions shown, the specific types of conditions may vary considerably with age. For example, a high proportion of fractures and dislocations among children and young adults involve the extremities. with short duration of stay, whereas among older persons many such injuries involve hips or bone processes for which the hospital stay may be long. It should also be recalled that these data do not include persons who were dead on discharge or died subsequently during the year before the interview. This exclusion undoubtedly influences the age distribution and length of stay by type of condition. For example, the proportion of persons over 65 years of age who have been hospitalized for heart conditions or neoplasms would be higher if the deceased were included, as in studies based on hospital records.

Condition for which hospitalized is shown in tables 21 and 22 according to whether or not the patient discharged was surgically treated for the hospitalized condition. Since surgical treatment in these tables pertains only to surgery for the hospitalized condition, a small percentage of these patients classified as not surgically treated actually had surgery performed on them during their hospital stay, but for a condition other than the one coded as the condition for which hospitalized. The difference in the total column of table 21 and that for table 23, which shows the number of discharges with surgical operation, indicates that an estimated 59,000 discharged patients had operations for conditions other than the condition for which they were hospitalized.

Surgical Operations

The number of hospital discharges and days, by whether or not the patient had surgery performed during the hospital stay by sex and age, is presented in tables 23 and 24.

Since, in the National Health Survey, patients hospitalized for delivery are considered as patients "with surgery," the rate of surgical operations was highest for females aged 15 to 44 years, 165.1 per 1,000 population (table 23).

Only 38.7 percent of patients discharged aged 65 years and over reported "surgery" performed during their hospital stay, while the percentage of all discharged patients who re-

¹See Appendix II for conditions included in each category.

ported "surgery" was 58.0 percent. A high proportion of discharges with surgery among children is accounted for by tonsillectomies, while in the 15-44 year age group deliveries accounted for a large proportion of the surgical cases.

In table 25, which shows the distribution of surgical operations by type, the percentage distribution for females is shown with deliveries included and also with deliveries excluded. This has been done because the inclusion of deliveries, which constitute about 44 percent of all female surgical operations, distorts the distribution so that no meaningful interpretation of the sex differential for other types of surgical procedures can be made.

Since up to 3 surgical procedures may be reported for any one discharge the total estimate of 12,006,000 surgical operations reported in this table exceeds by 482,000 the estimated number of discharged patients receiving surgery, shown in table 23.

POPULATION

The final tables in this report, tables 26-29, present population estimates by selected characteristics. These estimates, derived from the Health Interview Survey sample, are solely for the purpose of providing denominators for rate computations and are not to be considered as official population estimates.

APPENDIX I

TECHNICAL NOTES ON METHODS

Background of This Report

This report on hospital discharges is one of a series of statistical reports prepared by the U. S. National Health Survey which cover separate health-related topics. It is based on information collected in a continuing nationwide sample of households in the Health Interview Survey, which is one of the major projects of the U. S. National Health Survey.

The Health Interview Survey utilizes a questionnaire which elicits information on illnesses, injuries, chronic conditions, disability, medical care, and other health topics in addition to personal and demographic characteristics. As data relating to each of these various broad topics are tabulated and analyzed, separate reports are issued which cover one or more of the specific topics.

The population covered by the sample for the Health Interview Survey is the civilian noninstitutional population of the United States living at the time of interview. The sample does not include members of the Armed Forces, U. S. nationals living in foreign countries, or crews of vessels. It should also be noted that the estimates shown do not represent a complete count of discharges from short-stay hospitals during the two years since no adjustment has been made for household members who were hospitalized during the 6-month recall period but who died prior to the time the household was interviewed.

Statistical Design of the Health Interview Survey

General plan,—The sampling plan of the survey follows a multistage probability design which permits a continuous sampling of the civilian noninstitutional population of the United States. The first stage of this design consists of drawing a sample of 500 from the 1,900 geographically defined Primary Sampling Units (PSU's) into which the United States has been divided. A PSU is a county, a group of contiguous counties, or a Standard Metropolitan Statistical Area.

With no loss in general understanding, the remaining stages can be telescoped and treated in this discussion as an ultimate stage. Within PSU's then, ultimate stage units called segments are defined, also geographically, in such a manner that each segment contains an expected six households. Each week a random sample of about 120 segments is drawn. In the approximately 700 households in these segments, household members are interviewed concerning factors related to health.

Since the household members interviewed each week are a representative sample of the population, samples for successive weeks can be combined into

larger samples. Thus the design permits both continuous measurement of characteristics of high incidence or prevalence in the population and, through the larger consolidated samples, more detailed analysis of less common characteristics and smaller categories. The continuous collection has administrative and operational advantages as well as technical assets, since it permits field work to be handled with an experienced, stable staff,

Sample size and geographic detail.—The national sample plan over the two-year period ending June 26, 1960 includes approximately 245,000 persons from 75,000 households in 12,600 segments, with representation from every State. The sample was designed in such a fashion that tabulations can be provided for the four main regions and for urban and rural sectors of the United States.

Collection of data.—The field operations for the household survey are performed by the Bureau of the Census under specifications established by the National Health Survey. In accordance with these specifications the Bureau of the Census designs and selects the sample, conducts the field interviewing, carries out quality control procedures, and reviews and codes the questionnaires.

Processing of data.—The coded data are processed on electronic computers by the National Health Survey staff. Included in this processing are assignment of weights, ratio adjustments, and related procedures necessary to project the data to national estimates. Another phase of this processing procedure involves carrying out internal edits and consistency checks to insure that the data are not incorrect due to errors in recording responses, coding, or processing. No editing can, of course, be expected to remove error or bias in reporting by respondents, Finally, the weekly data are combined to provide quarterly and annual data and tabulations are prepared which give estimates of aggregates, rates, and other statistical measures.

Estimating methods.—Each statistic produced by the survey—for example, the number of discharges from short-stay hospitals for persons aged 15-24 years—is the result of two stages of ratio estimation.

The first stage ratio factor is: the 1950 decennial census population of the United States divided by the estimated 1950 population in the sample of 500 PSU's selected for the U. S. National Health Survey.

This factor is applied for some 50 color-residence classes.

The second stage ratio factors are: official Bureau of the Census estimates of the current population divided by estimates produced by the U. S. National Health Survey sample. These factors are computed for about 60 age-sex-color classes.

The effect of the ratio estimating process is to make the sample closely representative of the U. S. population by age, sex, color, and residence, thus reducing sampling variance.

The survey questionnaire uses a 12-month recall period for hospitalizations. That is, the respondent is asked to report hospitalizations which occurred during the 12 months prior to the week of interview. Information is also obtained as to the date of entry into the hospital and duration of stay. Analysis of this information, and also the results of special studies, has shown that there is an increase in underreporting of hospitalizations with increase in time interval between the discharge and the interview. Exclusive of the hospital experience of decedents, the net underreporting with a 12 months' recall is in the neighborhood of 10 percent, but underreporting of discharges within 6 months of the week of interview is estimated to be less than 5 percent. For this reason all of the data included in this report are based upon hospital discharges reported to have occurred within 6 months of the week of interview. Since the interviews were evenly distributed according to weekly probability samples throughout any 1 interviewing year, no seasonal bias was introduced by doubling the 6-month recall data to produce an annual estimate for that year of interviewing. Doubling the six months' data in effect imputes to the entire year preceding the interview the rate of hospital discharges actually observed during the 6 months prior to interview.

The basic statistical estimate presented in this report is the average annual number of hospital discharges experienced during a year by the population alive at the end of the year. The estimates for the two 1-year periods of interviewing, July 1958-June 1959 and July 1959-June 1960 were averaged to produce annual rates of hospital discharges with lower variances than would have been obtained from the use of a single year of data, As previously stated, the associated population is the average civilian noninstitutional population during the period July 1958-June 1960. The hospital data refer to hospital discharges that occurred during the year prior to the week of interview and therefore may be said to include discharges that took place from July 1957-June 1960. (Tabulated data include discharges occurring from January 1958-June 1960, but imputed from the 6month recall to have occurred during a 12-month period. This procedure introduces only a very slight bias in the estimates as a result of the gradual upward trend in hospital utilization.) It is recognized that some readers may wish to relate the data of this report to other information for which calendar year data are available. For such a purpose, the annual estimates presented here are perhaps best considered as average annual estimates for discharges occurring in the calendar years 1958 and 1959.

General Qualifications

Nonresponse.—Data are adjusted for nonresponse by a procedure which imputes to persons in a household which was not interviewed the characteristics of persons in households which were interviewed in the same segment. The total noninterview rate was 5 percent; 1 percent was refusal, and the other 4 percent

was primarily due to the failure to find any eligible household respondent after repeated trials.

The interview process,—The statistics presented in this report are based on replies secured in interviews in the sampled households. Each person 18 years of age and over, available at the time of interview, was interviewed individually. Proxy respondents within the household were employed for adults not available at the time of the interview and for children, provided the respondent was closely related to the person about whom information was being obtained.

Population figures. -- Some of the published tables include population figures for specified categories. Except for certain over-all totals which are adjusted to independent estimates, these figures are based on the sample of households in the U.S. National Health Survey. They are given primarily for the purpose of providing denominators for rate computation and populations for sampling errors, and for this purpose are more appropriate for use with the accompanying measurements of health characteristics than other population data which may be available. In some instances they will permit users to recombine published data into classes more suitable to their specific needs. The population figures differ from corresponding figures (which are derived from different sources) published in reports of the Bureau of the Census. For population data for general use, see the official estimates presented in Bureau of the Census reports in the P-20, P-25, and P-60 series.

Reliability of Estimates

Since the estimates are based on a sample, they differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and interviewing personnel and procedures. As in any survey, the results are also subject to measurement error.

The standard error is primarily a measure of sampling variability; that is, the variations that might occur by chance because only a sample of the population is surveyed. As calculated for this report, the standard error also reflects part of the variation which arises in the measurement process. It does not include estimates of any biases which might lie in the data. The chances are about 68 out of 100 that an estimate from the sample differs from the value obtained from a complete census by less than the standard error. The chances are about 95 out of 100 that the difference is less than twice the standard error and about 99 out of 100 that it is less than 2½ times as large.

In order to derive standard errors which would be applicable to a wide variety of health statistics and which could be prepared at a moderate cost, a number of approximations were required. As a result, the tables of standard errors shown in this Appendix should be interpreted as providing estimates of approximate standard errors, rather than as the precise standard errors for any specific statistic.

The following rules will enable the reader to determine the sampling errors for the data contained in this report;

1. Estimates of aggregates: Approximate standard errors of estimates of aggregates for the number

of hospital discharges and the number of hospital days are obtained from the appropriate columns of table I.

Example:

There were 19,875,000 discharges from shortstay hospitals. Since the standard error for this estimate is not shown in table I, it is necessary to interpolate between the standard error for 10,000,000 discharges which is 256,000 and the standard error for 20,000,000 discharges which is 352,000. Such interpolation gives 351,000 as the standard error for 19,875,000 discharges.

Table I. Standard errors of estimates of aggregates

(All numbers shown in thousands)									
Size of estimate	Hospital discharges and population estimates	Hospital days							
1.00	24 35 52 80 112 135 176 256 352 417 505	44 58 87 112 160 192 256 384 592 777 1,150							
100,000	560 640	2,080 3,840							

¹Standard errors for population estimates must be computed for all estimates except sex, age, race, and residence which are adjusted to Bureau of the Census figures so are not considered subject to sampling error.

2. Estimates of percentages based on hospital discharges; Approximate standard errors of the percentages shown in tables based on hospital discharges are given in the appropriate columns of table II.

Of the 12,509,000 discharges reported for females, 21.9 percent of these discharges were for the age group 15-24. Since neither the base nor the percentage is shown in table II it is necessary to interpolate. Interpolating between 10 percent and 25 percent we obtain 0.9 as the standard error of 21.9 percent with a base of 10,000,000 and 0.7 as the standard error of 21.9 percent with a base of 20,000,000. A final interpolation between these results yields 0.9 as the standard error of 21.9 percent with a base of 12,509,000 discharges.

3. Estimates of percentages based on hospital days: Approximate standard errors of the percentages shown in tables based on hospital days are given in the appropriate columns of table III.

Example:

Of the 166,935,000 days reported for both sexes, 7.5 percent of these days were for persons 75 years and over. Since neither the base nor the percentage is shown in table III we must interpolate. Interpolating between 5 percent and 10 percent we obtain 0.3 as the standard error of 7.5 percent with a base of 100,000,000 and 0.2 as the standard error of 7.5 percent with a base of 200,000,000. A final interpolation between these results yields 0.2 as the standard error of 7.5 percent with a base of 166,935,000 days.

4. Estimates of the number of hospital discharges as a rate of the population; Approximate standard errors for estimates of the number of discharges per 1,000 population are obtained in table II after converting the rate to a percentage. The standard error derived from table II must be multiplied by 10 so as to apply to a rate per 1,000 population.

Example:

For males aged 65-74 there were 160.6 discharges per 1,000 population. Converting the rate to a percent we obtain 16.1 percent with a base of 4,576,000 persons aged 65-74. Following

50,000	0.2	0.3	0.4	0.6	0.7				
100,000	0.1	0.2	0.3	0.4	0.5				
200,000	0.1	0.2	0.2	0.3	0.4				

the instructions in rule 2 results in a 1.2 percent standard error for 16.1 percent with a base of 4,576,000. Multiplying this result by 10 yields 12.0 as the standard error of the rate of 160.6 per 1,000 population with a base population of 4,576,000.

5. Estimate of the number of hospital days per discharge (average length of stay) or per 1,000 population: Approximate standard errors for estimates of the number of hospital days per discharge or per 1,000 population are obtained as follows:

(a) Obtain the standard error of the numerator (the total number of hospital days for the particular population group being studied) from table I. Divide the standard error by the numerator itself. Square the results.

(b) Obtain the standard error for the denominator (the population of the particular group being studied) from table I. Divide the standard error by the denominator itself. Square the results, (Note: Where the denominator is adjusted to Bureau of the Census figures (sex, age, race, and residence) and therefore is not considered subject to sampling error, this quantity is zero.)

(c) Add the answers from steps (a) and (b) above and extract the square root.

(d) Multiply the answer from step (c) by the rate. The result is the approximate standard error of the rate. This procedure normally gives an overestimate of the true sampling error.

Examples:

A. The average length of hospital stay per discharge among persons 45-54 years of age was 11.5 days (table 1). Utilizing Rule 1, the standard error for the numerator of 25,876,000 days is 701,000, and the standard error for the denominator of 2,246,000 discharges is 118,000. Completing the computation as follows:

$$11.5\sqrt{\left(\frac{701,000}{25,876,000}\right)^2 + \left(\frac{118,000}{2,246,000}\right)^2}$$

yields 0.68 as the standard error of 11.5 days of hospital stay.

B. There were 255,2 hospital days per year reported per 1,000 population aged 5-14 years (table 1). The standard error for the numerator of 8,928,000 days is 357,000, and the denominator, because it has been adjusted to Bureau of the Census population figures, is assumed to have no sampling error. Completing the computation as follows;

$$255.2\sqrt{\frac{357,000}{8,928,000}^2+0}$$

yields 10.2 as the standard error of 255.2 hospital days per 1,000 population 5-14 years of age.

APPENDIX II

DEFINITIONS OF CERTAIN TERMS USED IN THIS REPORT

Terms Relating to Hospitalization

Hospital discharge. - A hospital discharge is the completion of any continuous period of stay of one or more nights in a hospital, as an inpatient, except the period of stay of a well, newborn infant. A hospital discharge is recorded whenever a present member of the household is reported to have been discharged from a hospital in the 12-month period prior to the interview week. (For this report estimates were based on discharges which occurred during the 6-month period prior to the interview. See Appendix 1.)

Hospital .- For this survey a hospital is defined as any institution meeting one of the following cri-teria: (1) named in the listing of hospitals in the 1957-1959 Guide Issues of Hospitals, the Journal of the American Hospital Association; (2) named in the listing of hospitals in the 1957-1960 Directories of the American Osteopathic Hospital Association; or (3) named in the annual inventory of hospitals and related facilities submitted by the States to the Division of Hospital and Medical Facilities of the U.S. Public Health Service in conjunction with the Hill-Burton program.

Hospital ownership. -- Hospital ownership is a classification of hospitals according to the type of organization that controls and operates the hospital, The category to which an individual hospital is assigned and the definition of these categories follows the usage of the American Hospital Association.

Type of hospital service. - Type of hospital service is a classification of hospitals according to the predominant type of cases for which they provide care. The category to which an individual hospital is assigned and the definition of these categories follows the usage of the American Hospital Association,

Short-stay hospital.—A short-stay hospital is one for which the type of service is: general; maternity; eye, ear, nose, and throat; children's; osteopathic hospital; or hospital department of institution.

Hospital day. - A hospital day is a day in which a person is confined to a hospital. The day is counted as a hospital day only if the patient stays overnight. Thus, a patient who enters the hospital on Monday afternoon and leaves Wednesday noon is considered to have had two hospital days,

Estimates of the total number of hospital days are derived by summing the days for all hospital discharges, (See definition of "Hospital discharge,")

Length of hospital stay.—The length of hospital stay is the duration in days, exclusive of the day of discharge, of a hospital discharge. (See definition of "Hospital discharge.")

<u>Average length of stay.—The average length of</u>

stay per discharged patient is computed by dividing

the total number of hospital days for a specified group by the total number of discharges for the same group.

Condition for which hospitalized,-The condition for which hospitalized is the condition responsible for a hospitalization. If there is more than one hospital condition for any one episode, only that one believed to be chiefly responsible for the stay in the hospital is tabulated. If a person enters a hospital for diagnostic tests, or for an operation, the condition that made the tests or operation necessary is considered to be the condition for which hospitalized,

Normal delivery in a hospital is included as a condition for which hospitalized but care of the well, newborn infant is not.

Conditions, except impairments, are coded by type according to the International Classification of Diseases, with certain modifications adopted to make the code more suitable for a household-interview type survey. For survey results for the two years ending June 30, 1960, the 1955 Revision of the International Classification was used, Impairments are coded according to a special supplementary classification.

The list at the end of this appendix shows the code numbers of the International Classification and special supplementary classification of impairments included in the condition groups used in this report.

Surgical operation.—A surgical operation includes any cutting or piercing of the skin or other tissue, stitching of cuts or wounds, and setting of fractures and dislocations, Deliveries are counted as operations, Injections and transfusions, however, are not included, nor are routine circumcisions.

Only operations performed in hospitals upon inpatients are included.

Operations are classified by type according to a condensed version of "Classification Codes for Surgical Operations and Procedures," published by the Bureau of Medical Services, Public Health Service, Department of Health, Education, and Welfare, September 1954,

Demographic, Social, and Economic Terms

Age. - The age recorded for each person is the age at last birthday. Age is recorded in single years and grouped in a variety of distributions depending upon the purpose of the table,

Race,-Race is recorded as "White," or "Nonwhite," "Nonwhite" includes Negro, American Indian, Chinese, Japanese, and so forth. Mexican persons are included with "White" unless definitely known to be Indian or other nonwhite race.

Income of family or of unrelated individuals. - Each member of a family is classified according to the total income of the family of which he is a member. Within the household all persons related to each other by blood, marriage, or adoption constitute a family. Unrelated individuals are classified according to their own income.

The income recorded is the total of all income received by members of the family (or by an unrelated individual) in the 12-month period ending with the week of interview. Income from all sources is included, e.g., wages, salaries, rents from property, pensions, help from relatives, and so forth.

Education of family head or of unrelated individuals.—Each member of a family is classified according to the education of the head of the family of which he is a member. Within the household all persons related to each other by blood, marriage, or adoption constitute a family. Unrelated individuals are classified according to their own education.

The categories of educational status show the highest grade of school completed. Only grades completed in regular schools, where persons are given a formal education, are included. A "regular" school is one which advances a person toward an elementary or high school diploma, or a college, university, or professional school degree. Thus, education in vocational, trade, or business schools outside the regular school system is not counted in determining the highest grade of school completed.

Usual activity status.—All persons 6 years old or over are classified according to their usual activity status during the 12-month period prior to the week of interview. The "usual" activity status, in case more than one is reported, is the one at which the person spent the most time during the 12-month period.

The categories of usual activity status are; usually working, usually going to school and preschool, usually keeping house, retired, and other. For several reasons these categories are not comparable with somewhat similarly named categories in official Federal labor force statistics. First, the responses concerning usual activity status are accepted without detailed questioning, since the objective of the question is not to estimate the numbers of persons in labor force categories but to identify crudely certain population groups which may have differing health problems. Second, the figures represent the usual activity status over the period of an entire year, whereas official labor force statistics relate to a much shorter period, usually one week. Finally, in the definitions of the specific categories which follow, certain marginal groups are classified in a different manner to simplify the procedures.

- Usually working.—A term applied to an individual, 17 years of age or older, who was gainfully employed as a paid employee, a self-employed person, or as a worker in a family business for more than half of the 12 months prior to the interview. A person who does only volunteer or unpaid work—such as work in his own home or work for the church or community—is not considered gainfully employed.
- 2. Usually going to school and preschool.—This group is defined by age. All persons under 17 years of age fall into this category. Any person 17 years old or over who reports his major activity as usually going to school is classified as "Other."

- Usually keeping house includes any activity described as "keeping house" which cannot be classified as "working" or "going to school,"
- 4. Retired includes persons 45 years old or over who consider themselves to be retired. In case of doubt, a person 45 years old or over is counted as retired if he, or she, has either voluntarily or involuntarily stopped working, is not looking for work, and is not described as "keeping house." A retired person may or may not be unable to work.
- 5. Other includes persons 17 years of age or over not classed in any of the other categories, Examples of inclusions are: a person who states that he spent most of the past 12 months looking for work or going to school, a person doing volunteer work only, a person under 45 years of age who describes himself as "retired" or "taking it easy," a person under 45 years of age who is described as "unable to work," or a person 45 years of age or over who describes himself as "unable to work" and is not "retired,"

Household composition,—Household composition defines the individual's relationship to other persons within the same household. For this report the definition of household composition consists of three categories as follows:

- Living alone.—Persons living in one-member households.
- Living with nonrelatives.—Persons living in a household with another person or persons, none of whom are related to him by blood, marriage, or adoption.
- Living with relatives.—Persons living in a household with another person or persons, of whom one or more are related to him by blood, marriage, or adoption.

Location of Residence Terms

Urban and rural residence.—The definition of urban and rural areas used in the U. S. National Health Survey is the same as that used in the 1950 Census, According to this definition, the urban population comprises all persons living in (a) places of 2,500 inhabitants or more incorporated as cities, boroughs, and villages; (b) incorporated towns of 2,500 inhabitants or more except in New England, New York, and Wisconsin, where "Towns" are simply minor civil divisions of counties; (c) the densely settled urban fringe, including both incorporated and unincorporated areas, around cities of 50,000 or more; and (d) unincorporated places of 2,500 inhabitants or more outside any urban fringe. The remaining population is classified as rural.

Farm and nonfarm residence.—The rural population may be subdivided into the rural-farm population, which comprises all rural residents living on farms, and the rural-nonfarm population, which comprises the remaining rural population.

In deciding whether the members of a household reside on a farm or a ranch, the statement of the household respondent that the house is on a farm or ranch is accepted, with the following exception. A house occupied by persons who pay cash rent for

house and yard only is not counted as a farm or ranch even if the surrounding area is farm land. This special case does not cover: (1) the living quarters of a tenant farmer who rents farm land as well as house and yard; (2) the quarters of a hired hand who receives living quarters on a farm as part of his compensation; or (3) separate living quarters inside a structure which is classified as on a farm. In all these cases the living quarters are counted as on a farm.

Region.—The least detailed classification of the population by geographic area of residence is provided by the grouping of states into four major regions. These regions correspond to those used by the Bureau of the Census. They are as follows:

States Included

Northeast

Maine, New Hampshire, Vermont, Massachusetts, Rhode Island,

Region States Included

South

Northeast—Con. Connecticut, New York, New Jersey,
Pennsylvania
North Central Michigan, Ohio, Indiana, Illinois,
Wisconsin, Minnesota, Iowa,
Macauri, North Dakota

Missouri, North Dakota, South Dakota, Nebraska, Kansas Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky,

Tennessee, Alabama, Mississippi, Arkansas, Louisiana, Oklahoma, Texas

West Montana, Idaho, Wyoming, Colorado, New Mexico, Arlzona, Utah, Nevada, Alaska, Washington,

Oregon, California, Hawaii

Condition for Which Hospitalized	International Classification of Diseases
	Code numbers 1

	Code numbers 1
Infective and parasitic diseases	001-138, except 083.1, 083.2
Malignant neoplasms	140-205
Benign and unspecified neoplasms	210-239
Diabetes mellitus	260-269
Other endocrine, allergic, and metabolic disorders	240-259,270-289
Mental and personality disorders	083.1, 083.2, 300-326, 790, X14-X19
Intracranial lesions	330-334
Diseases of the eye	370-388, X00-X05
Other diseases of nervous system and sense organs	340-369, 390-396, 780, 781, X06-X13
Heart diseases	410-443
Hypertension without heart involvement	444-447
Varicose veins (excluding hemorrhoids)	460, 462
Hemorrholds	461
Other circulatory diseases	400-402, 450-456, 463-468, 782
Upper respiratory conditions	470-475, 510-517
Other respiratory conditions	480-502, 518-527, 783, X36
Ulcer of stomach and duodenum	540-542
Appendicitis	550-553
Hernia	560, 561
Diseases of the gallbladder	584-586
Other digestive system conditions	530-539, 543-545, 570-583, 587, 784, 785, X35
Male genital disorders	610-617
Female breast and genital disorders	620-637
Other genitourinary conditions	590-609 (620, 621 males), 786, 789, X37, X38
Deliveries	660, 670-678
Complications of pregnancy and the puerperium	640-652, 680-689
Diseases of the skin	690-716
Arthritis, all forms	720-725
Other diseases of bones and joints	730-733, 735, 738 (N800-N829) ²
Other diseases of the musculoskeletal system	726-727, 740-744, 787, X20-X34, X70-X89
Fractures and dislocations	N800-N839 ³
Other current injuries	N840~N999 ³

¹Conditions except impairments, are coded according to the International Classification of Diseases with certain modifications, and impairments are coded according to a special supplementary classification referred to as the "X-Code." Numbers preceded by the letter "X" refer to this special supplementary classification. Copies of this code are available upon request. If the conditions included in an "ICD" number are equivalent to those included in an "X-Code" category, the ICD number is not used.

3 Other than .9 in the 4th digit.

All other ICD and "X-Code" numbers

All other conditions and observations

APPENDIX III

QUESTIONNAIRE

The items below show the exact content and wording of the questionnaire used in the household survey. The actual questionnaire is designed for a household as a unit and includes additional spaces for reports on more than one person.

SELECTED REPORTS FROM THE U.S. NATIONAL HEALTH SURVEY

Public Health Service Publication No. 584

Series A (Program descriptions, survey designs, concepts, and definitions)

- No. 1. Origin and Program of the U. S. National Health Survey. 25 conts.
- No. 2. The Statistical Design of the Health Household-Interview Survey. 35 cents.
- No. 3. Concepts and Definitions in the Health Household-Interview Survey. 30 cents.

Series B (Health Interview Survey results by topics)

- No. 6. Acute Conditions, Incidence and Associated Disability, United States, July 1957-June 1958. 35 cents.
- No. 7. Hospitalization, Patients Discharged From Short-Stay Hospitals, United States, July 1957-June 1958. 30 cents.
- No. 8. Persons Injured by Class of Accident, United States, July 1957-June 1958. 40 cents.
- No. 9. Impairments by Type, Age, and Sex, United States, July 1957-June 1958. 25 cents.
- No. 10. Disability Days, United States, July 1957-June 1958. 40 cents.
- No. 11. Limitation of Activity and Mobility Due to Chronic Conditions, United States, July 1957-June 1958. 30 cents.
- No. 12. Chronic Respiratory Conditions Reported in Interviews, United States, July 1957-June 1958. 30 cents.
- No. 13. Heart Conditions and High Blood Pressure Reported in Interviews, United States, July 1957-June 1958. 30 cents.
- No. 14. Dontal Care, Interval and Frequency of Visits, United States, July 1957-June 1959. 35 cents.
- No. 15. Dental Care, Volume of Visits, United States, July 1957-June 1959. 35 cents.
- No. 16. Types of Injuries, Incidence and Associated Disability, United States, July 1958-June 1959. 30 cents.
- No. 17. Poptic Ulcors Reported in Interviews, United States, July 1957-June 1959. 25 cents.
- No. 18. Acute Conditions, Incidence and Associated Disability, United States, July 1958-June 1959. 30 cents.
- No. 19. Volume of Physician Visits, United States, July 1957-June 1959. 40 cents.
- No. 20/ Arthritis and Rhommatism Reported in Interviews, United States, July 1957-June 1959. 25 cents.
- No. 21. Diahetes Reported in Interviews, United States, July 1957-June 1959. 25 cents.
- No. 22. Loss of Teeth, United States, July 1957-June 1958. 25 cents.
- No. 23. Acute Conditions, Geographic Distribution, United States, July 1958-June 1959. 30 cents.
- No. 24. Acute Conditions, Seasonal Variations, United States, July 1957-June 1960. 35 cents.
- No. 25. Hernias Reported in Interviews, United States, July 1957-June 1959. 25 conts.
- No. 26. Interim Report on Health Insurance, United States, July-December 1959. 45 conts.
- No. 27. Distribution and Use of Henring Aids, Wheel Chairs, Braces, and Artificial Limbs, United States, July 1958-June 1959. 25 cents.
- No. 28. Persons Receiving Care at Home, United States, July 1958-June 1959. 30 cents.
- No. 29. Disability Days, United States, July 1959-June 1960. 40 cents.
- No. 30. Proportion of Hospital Bill Paid By Insurance, Patients Discharged From Short-Stay Hospitals, United States, July 1958-June 1960. 40 cents.
- No. 31. Duration of Limitation of Activity Due to Chronic Conditions, United States, July 1959-June 1960. 36 cents.
- No. 32. Hospital Discharges and Length of Stay: Short-Stay Hospitals, United States, 1958-1960.

Series C (Health Interview Survey results for population groups)

- No. 1. Children and Youth, Selected Health Characteristics, United States, July 1957-June 1958. 35 cents.
- No. 2. Votorans, Health and Medical Care, United States, July 1957-June 1958. 40 cents.
- No. 3. The Hawaii Health Survey, Description and Selected Results, Oahu, Hawaii, October 1958-September 1959. 40 cents.
- No. 4. Older Persons, Selected Health Characteristics, United States, July 1957-June 1959. 45 cents
- No. 5. Selected Health Characteristics by Area, Geographic Regions and Urban-Rural Residence, United States, July 1957-June 1959. 35 cents.
- No. 6. Selected Health Characteristics by Aren, Geographic Divisions and Large Metropolitan Areas, United States, July 1957-June 1959. 35 conts.
- No. 7. Currently Employed Persons, Illness and Work-Loss Days, United States, July 1959-June 1960.

Series D (Developmental and Evaluation Reports)

- No. 1. A Study of Special Purpose Medical-History Techniques. 30 conts.
- No. 2. Co-operation in Health Examination Surveys. 35 cents.
- No. 3. Hospital Utilization in the Last Year of Life. 30 cents.
- No. 4. Reporting of Hospitalization in the Health Interview Survey. 50 cents.
- No. 5. Health Interview Responses Compared With Medical Records. 45 cents.
- No. 6. Attitudes Toward Co-operation in a Health Examination Survey. 35 cents.
- No. 7. Evaluation of a Single-Visit Cardiovascular Examination. 30 cents.

Catalog Card

U. S. National Health Survey

Hospital discharges and length of stay: short-stay hospitals, United States, 1958-1960. Statistics for short-stay hospitals on patients discharged and days of hospital stay by selected characteristics of the patients and types of hospitals. Based on data collected in household interviews during July 1958-June 1960. Washington, U.S. Dept. of Health, Education, and Welfare, Public Health Service, 1962.
